BITUMEN RESOURCES OF THE UPPER DEVONIAN
GROSMONT FORMATION, Tp 88 TO 98, NORTHERN ALBERTA

T. YOON
Alberta Energy and Natural Resources

INTRODUCTION

As part of the ARC/AENR joint Regional Subsurface Geology Program, a bitumen resources study of the Grosmont Formation was undertaken by Mr. T. Yoon of Alberta Energy and Natural Resources under the general supervision of Dr. R.S. Harrison, Alberta Research Council, during the period between November 1984 and April 1985. The study reflects the specific interest of AENR's Mineral Agreement Branch in the bitumen potential of the northern portion of the Grosmont belt.

In spite of various studies and ever-increasing interest in the Grosmont bitumen resources, reserve-related data has not been publicly available. ERCB does not publish the Paleozoic reserve data and is not at the present time in a position to provide specific data on a regional basis.

The study area lies between TP 88 to 98, R 19 to 26, W 4 M (figure 1). The area covers approximately 571 000 hectares (62 Tp) in the southeastern part of the Wabasca North Oil Sands area, where the prolific Liege gas field is located. Approximately one-quarter of the study area is presently held as oil sand leases by several companies.

An initial review of all wells (roughly 350) in the study area identified approximately 140 wells from which relevant data was available. Many of these wells were aimed at gas-bearing Cretaceous and uppermost Grosmont zones in the Liege field and bitumen-bearing Nisku zones in the western part of the study area. The raw data for the study was collected from AENR, and ERCB data files at ARC, exclusive of operators' proprietary technical information.

The following information is contained in this report:

- (1) Computer-generated isopach maps of the Upper Grosmont G3, G2 and G1 stratigraphic units.
- (2) Computer-generated hydrocarbon pore volume maps for the Upper Grosmont G3, G2 and G1 units.
- (3) A table of stratigraphic picks used for the generation of the isopach maps (Table I).
- (4) A table of hydrocarbon pore volumes and potential pay thickness of the G3, G2 and G1 units in each study well (Table 2).
- (5) A table of generalized reservoir characteristics (Table 3a, 3b).
- (6) A table listing wells in the study area for which core analyses data is available (Table 4).

GEOLOGICAL SETTING

The crude bitumen reserves of interest in this study area are contained within southwesterly dipping Paleozoic platform carbonates which are unconformably overlain by a Cretaceous clastic sequence. The specific horizon of interest is the dolomitized Upper Devonian Grosmont Formation.

The eastern updip margin of the Grosmont is truncated by an erosional unconformity, the development of which undoubtedly gave rise to extensive leaching and the development of high secondary porosity. The Grosmont forms an erosional high on the pre-Cretaceous surface and appears to have been a major trap for the accumulation of oil (bitumen) in the study area.

The Grosmont Formation, a shallow marine, carbonate-platform sequence with a total thickness of approximately 170 to 180 meters, is underlain by the deeper water calcareous shales and argillaceous limestones of the Ireton Formation and generally separated from the overlying Nisku Formation by a relatively thin shale horizon.

The primary stratigraphic units of interest in this study are, in descending order, the G3, G2 and G1 units of the Upper Grosmont. These carbonate units are separated by thin but widespread calcareous shale horizons.

On a regional scale the bitumen pay is bounded by the pre-Cretaceous unconformity or by the gas-bitumen contact at + 250 meters (which can vary by 20 to 30 meters), and basally bounded by the bitumen-water contact at approximately + 160 meters (which can vary by 10 to 20 meters). Total dissolved solids of the Grosmont Formation water range from 3000 to 70 000 mg/l. Water resistivity ranges from 0.05 to 2.00 in the study area.

EVALUATION OF BITUMEN RESOURCES

This study was aimed at gaining an understanding of the distribution of bitumen resources contained in the Upper Grosmont units based on a "quick-look" approach.

Clean carbonate zones were identified on logs as possible bitumen-bearing units. Assuming that the pore volume contains only bitumen and water, the bitumen saturation of a carbonate could be determined for known values of water saturation and porosity.

Using porosity and bitumen saturation cut-offs of 6 percent and 50 percent respectively, average porosity and bitumen saturation values for each unit were manually determined from compensated Neutron-Formation Density logs and complemented by the very limited data available from actual core analyses. In addition, generalized regional reservoir characteristics were also summarized and used for areas with

little well control (Table 3a, 3b).

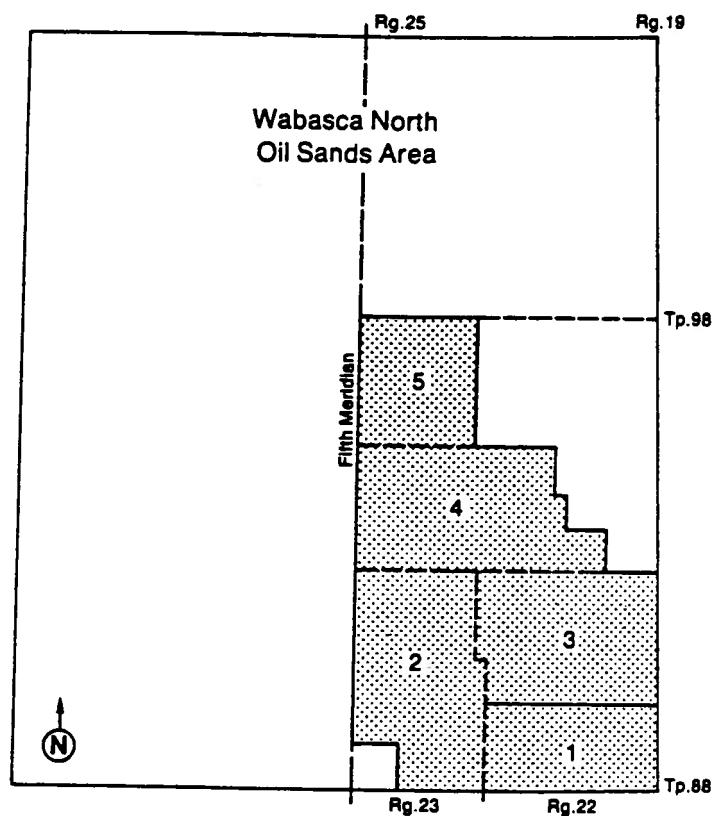

Less than 30 core analyses provided useful data for this study. Average regional bitumen saturation values were applied to uncored and unanalysed wells based on the average values determined at the nearest cored and analysed wells. Due to the scarcity of core analyses, it was necessary to develop a method for rough evaluation of the bitumen pay based on geophysical logs. Resistivity logs were compared with core analyses to determine bitumen saturation versus resistivity relationships. An approximate value of 100 ohms was found to satisfy the bitumen saturation cut-off (50 percent). Bitumen resources in partially flushed zones were included for this estimate, but not those from flushed zones.

SUMMARY OF FINDINGS

Within the total Upper Grosmont sequence, hydrocarbon pore volume values range from 2.5 meters to 9.0 meters with an average of approximately 6.0 meters. Maximum HPV of the G3, G2 and G1 units is approximately 12 meters, 4 meters and 2 meters, respectively. Actual pay thickness varies considerably from one Grosmont unit to the next, with the overall pay thicknesses in the Upper Grosmont ranging from 25 meters to over 80 meters.

The G3 unit is thick and rich in bitumen accumulation, but is less attractive for reservoir stimulation due to proximity of the unconformity and possible thief zones.

The G2 unit appears to be an economically attractive reservoir. There is relatively thick laterally extensive pay, with only moderate water saturation. The unit also contains less gas in comparison with the overlying G3 horizon. The G1 unit generally exhibits relatively low porosity and bitumen saturation and significantly thinner potential pay than either the G2 or G3 units.

Table 3a

GROSMONT BITUMEN STUDY

Generalized Reservoir Characteristics
for each stratigraphic unit

<u>Unit</u>	<u>Porosity (%)</u>	<u>Bitumen Saturation (%)</u>
G3	- Average 18 - upper half - 20 - lower half - 16	- Average 60-80 - higher close to the eastern erosional edge
G2	- Average 14 - top - 20 - base- 6	- east: 70-80 - west as low at 10
G1	- generally low - 20 to 30 where moldic and fracture porosities present	- generally low - close to the erosional edge averages 60-70

Table 3b

Generalized Reservoir Characteristics for each subdivision of the study area (Figure 1).

Area #1

<u>Unit</u>	<u>(%) Por.</u>	<u>Max. Bitumen Sat. (%)</u>	<u>Water Sat. (%)</u>	<u>Remarks</u>
G3	24	92	8	Sw (to 35%) plus some gas
G2	16	90	10	Sw (to 25%) plus some gas
G1	15	87	13	Some gas

Area #2

<u>Unit</u>	<u>(%) Por.</u>	<u>Max. Bitumen Sat. (%)</u>	<u>Water Sat. (%)</u>	<u>Remarks</u>
G3	24	93	7	Sw (to 22%) plus some gas
G2	12	85	15	Partially flushed (Sw: to 30%), flushed (Sw: to 67%)
G1	Flushed (Sw: to 64%)			-----

Area #3

<u>Unit</u>	<u>(%) Por.</u>	<u>Max. Bitumen Sat. (%)</u>	<u>Water Sat. (%)</u>	<u>Remarks</u>
G3	21	94	6	Gas saturation: to 30%
G2	13	89	11	Gas saturation: to 30%
G1	16	93	7	Partially flushed: Sw to 36%

Area #4

<u>Unit</u>	<u>(%) Por.</u>	<u>Max. Bitumen Sat. (%)</u>	<u>Water Sat. (%)</u>	<u>Remarks</u>
G3	19	70	6	Gas saturation: to 30%
G2	14	60	6	Gas saturation: to 40%
G1	12	70	6	Gas saturation: to 30%

Area #5

<u>Unit</u>	<u>(%) Por.</u>	<u>Max. Bitumen Sat. (%)</u>	<u>Water Sat. (%)</u>	<u>Remarks</u>
G3	-----N/A-----			
G2	16	63	10	Some gas
G1	15	50	20	Some gas

LIST OF CORE ANALYSES

Table No.4. a) well name & location.
 b) core interval.
 c) total length.
 d) interval length tested.
 e) units the core covered.
